April 19, 2025

```
[1]: import numpy as np
  import pandas as pd
  import platform
  import statsmodels
  print('Python version: ', platform.python_version())
  print('numpy version: ', np.__version__)
  print('pandas version: ', pd.__version__)
  print('statsmodels version: ', statsmodels.__version__)
```

Python version: 3.11.4 numpy version: 1.24.4 pandas version: 2.0.3 statsmodels version: 0.14.0

1 TikTok project: Regression modeling

The purpose of this project is to demostrate knowledge of EDA and regression models.

The goal is to build a logistic regression model and evaluate the model. This activity has three parts:

Part 1: EDA & Checking Model Assumptions * What are some purposes of EDA before constructing a logistic regression model?

Part 2: Model Building and Evaluation * What resources do you find yourself using as you complete this stage?

Part 3: Interpreting Model Results

- What key insights emerged from your model(s)?
- What business recommendations do you propose based on the models built?

2 Build a regression model

2.0.1 Task 1. Imports and loading

Import the data and packages that you've learned are needed for building regression models.

```
[1]: # Import packages for data manipulation import numpy as np
```

```
# Import packages for data visualization
import seaborn as sns
import matplotlib.pyplot as plt

# Import packages for data preprocessing
from sklearn.utils import resample
from sklearn.preprocessing import OneHotEncoder
from sklearn.feature_extraction.text import CountVectorizer, TfidfVectorizer

# Import packages for data modeling
from sklearn.metrics import classification_report
from sklearn.linear_model import LogisticRegression
from sklearn.model_selection import train_test_split
from sklearn.metrics import confusion_matrix, ConfusionMatrixDisplay
```

Load the TikTok dataset.

```
[3]: # Load dataset into dataframe
data = pd.read_csv("tiktok_dataset.csv")
```

Consider the questions in your planning to reflect on the Analyze stage.

In this stage, consider the following question where applicable to complete your code response:

• What are some purposes of EDA before constructing a logistic regression model?

Response:

The purposes of EDA before constructing a logistic regression model are

- 1) to identify data anomalies such as outliers and class imbalance that might affect the modeling;
- 2) to verify model assumptions such as no severe multicollinearity.

2.0.2 Task 2a. Explore data with EDA

Analyze the data and check for and handle missing values and duplicates.

Inspect the first five rows of the dataframe.

```
[6]: # Display first few rows data.head()
```

```

Check class balance of the target variable. Remember, the goal is to predict whether the user of a given post is verified or unverified.

```
[50]: # Check class balance data["verified_status"].value_counts(normalize=True)
```

[50]: verified status

not verified 0.93712 verified 0.06288

Name: proportion, dtype: float64

Approximately 94.2% of the dataset represents videos posted by unverified accounts and 5.8% represents videos posted by verified accounts. So the outcome variable is not very balanced.

Use resampling to create class balance in the outcome variable, if needed.

```
[15]: # Use resampling to create class balance in the outcome variable, if needed
      # Identify data points from majority and minority classes
      data majority = data[data["verified status"] == "not verified"]
      data_minority = data[data["verified_status"] == "verified"]
      # Upsample the minority class (which is "verified")
      data_minority_upsampled = resample(data_minority,

                                                                     1.000000
```

Visualize a correlation heatmap of the data.

One of the model assumptions for logistic regression is no severe multicollinearity among the features. Take this into consideration as you examine the heatmap and choose which features to proceed with.

Question: What variables are shown to be correlated in the heatmap?

Response: The above heatmap shows that the following pair of variables are strongly correlated: video_view_count and video_like_count (0.86 correlation coefficient).

One of the model assumptions for logistic regression is no severe multicollinearity among the features. To build a logistic regression model that meets this assumption, you could exclude video_like_count. And among the variables that quantify video metrics, you could keep video_view_count, video_share_count, video_download_count, and video_comment_count as features.

2.0.4 Task 3a. Select variables

Set your Y and X variables.

Select the outcome variable.

```
[29]: # Select outcome variable
y = data_upsampled["verified_status"]
```

Select the features.

```
[31]:
         video_duration_sec claim_status author_ban_status video_view_count \
                          59

      4
                                                                        56167.0
                          19
                                     claim
                                                       active
         video_share_count video_download_count video_comment_count
      0
                      241.0
                                               1.0
                                                                     0.0
                    19034.0
      1
                                            1161.0
                                                                   684.0
      2
                     2858.0
                                             833.0
                                                                   329.0
      3
                    34812.0
                                            1234.0
                                                                   584.0
                     4110.0
                                             547.0
                                                                   152.0
```

Important note: The # and video_id columns are not selected as features here, because they do not seem to be helpful for predicting whether a video presents a claim or an opinion. Also, video_like_count is not selected as a feature here, because it is strongly correlated with other features, as discussed earlier. And logistic regression has a no multicollinearity model assumption that needs to be met.

2.0.5 Task 3b. Train-test split

Split the data into training and testing sets.

```
[33]: # Split the data into training and testing sets
X_train, X_test, y_train, y_test = train_test_split(X, y, test_size=0.25, □
→random_state=0)
```

Confirm that the dimensions of the training and testing sets are in alignment.

```
[35]: # Get shape of each training and testing set
X_train.shape, X_test.shape, y_train.shape, y_test.shape
```

```
[35]: ((26826, 7), (8942, 7), (26826,), (8942,))
```

Important notes:

- The number of features (7) aligns between the training and testing sets.
- The number of rows aligns between the features and the outcome variable for training (26826) and testing (8942).

2.0.6 Task 3c. Encode variables

Check the data types of the features.

```
[37]: # Check data types
      X_train.dtypes
                                int64
[37]: video_duration_sec
      claim_status
                                object
      author_ban_status
                                object
                              float64
      video_view_count
      video_share_count
                              float64
      video_download_count
                              float64
      video_comment_count
                              float64
      dtype: object
[39]: # Get unique values in `claim_status`
      X_train["claim_status"].unique()
[39]: array(['opinion', 'claim'], dtype=object)
[41]: # Get unique values in `author ban status`
      X_train["author_ban_status"].unique()
```

[41]: array(['active', 'under review', 'banned'], dtype=object)

As shown above, the claim_status and author_ban_status features are each of data type object currently. In order to work with the implementations of models through sklearn, these categorical features will need to be made numeric. One way to do this is through one-hot encoding.

Encode categorical features in the training set using an appropriate method.

```
[43]: # Select the training features that needs to be encoded
X_train_to_encode = X_train[["claim_status", "author_ban_status"]]

# Display first few rows
X_train_to_encode.head()
```

```
[43]:
            claim_status author_ban_status
      33058
                  opinion
                                      active
      20491
                  opinion
                                      active
                  opinion
      25583
                                      active
      18474
                  opinion
                                      active
      27312
                  opinion
                                      active
```

```
[45]: # Set up an encoder for one-hot encoding the categorical features
      X_encoder = OneHotEncoder(drop='first', sparse_output=False)
[47]: # Fit and transform the training features using the encoder
      X_train_encoded = X_encoder.fit_transform(X_train_to_encode)
[49]: # Get feature names from encoder
      X_encoder.get_feature_names_out()
[49]: array(['claim_status_opinion', 'author_ban_status_banned',
             'author_ban_status_under review'], dtype=object)
[51]: # Display first few rows of encoded training features
      X_train_encoded
[51]: array([[1., 0., 0.],
             [1., 0., 0.],

```

Check the data type of the outcome variable.

```
[59]: # Check data type of outcome variable y_train.dtype
```

- [59]: dtype('0')
- [61]: # Get unique values of outcome variable y_train.unique()
- [61]: array(['verified', 'not verified'], dtype=object)

A shown above, the outcome variable is of data type object currently. One-hot encoding can be used to make this variable numeric.

Encode categorical values of the outcome variable the training set using an appropriate method.

```
[63]: # Set up an encoder for one-hot encoding the categorical outcome variable y_encoder = OneHotEncoder(drop='first', sparse_output=False)
```

[65]: array([1., 1., 1., ..., 1., 1., 0.])

2.0.7 Task 3d. Model building

Construct a model and fit it to the training set.

```
[67]: # Construct a logistic regression model and fit it to the training set log_clf = LogisticRegression(random_state=0, max_iter=800).fit(X_train_final, y_train_final)
```

2.0.8 Taks 4a. Results and evaluation

Evaluate your model.

Encode categorical features in the testing set using an appropriate method.

```
[69]: # Select the testing features that needs to be encoded
X_test_to_encode = X_test[["claim_status", "author_ban_status"]]
```

```
# Display first few rows
      X_test_to_encode.head()

                   verified
      Name: verified_status, Length: 8942, dtype: object
```

Encode the true labels of the testing set so it can be compared to the predictions.

```
[87]: # Encode the testing outcome variable
# Notes:
# - Adjusting the shape of `y_test` before passing into `.transform()`, sinceurit takes in 2D array
# - Using `.ravel()` to flatten the array returned by `.transform()`, so thature it can be used later to compare with predictions
y_test_final = y_encoder.transform(y_test.values.reshape(-1, 1)).ravel()
# Display the encoded testing outcome variable
y_test_final
```

```
[87]: array([1., 1., 1., ..., 0., 1., 1.])
```

Confirm again that the dimensions of the training and testing sets are in alignment since additional features were added.

```
[89]: # Get shape of each training and testing set
X_train_final.shape, y_train_final.shape, X_test_final.shape, y_test_final.shape
```

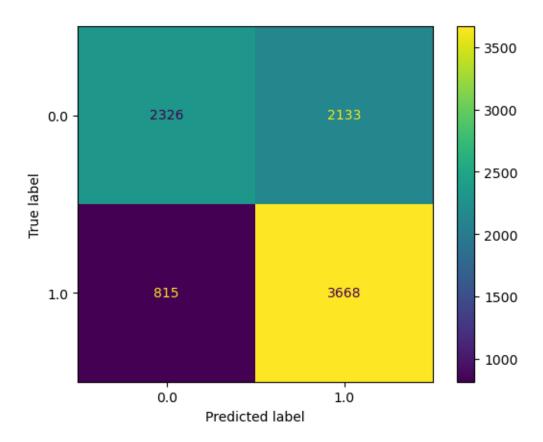

```
[89]: ((26826, 8), (26826,), (8942, 8), (8942,))
```

Important note:

- The number of features (8) aligns between the training and testing sets.
- The number of rows aligns between the features and the outcome variable for training (26826) and testing (8942).

2.0.9 Task 4b. Visualize model results

Create a confusion matrix to visualize the results of the logistic regression model.

[93]: (3758+2044) / (3758 + 725 + 2044 + 2415)

[93]: 0.6488481324088571

Important notes:

The upper-left quadrant displays the number of true negatives: the number of videos posted by unverified accounts that the model accurately classified as so.

The upper-right quadrant displays the number of false positives: the number of videos posted by unverified accounts that the model misclassified as posted by verified accounts.

The lower-left quadrant displays the number of false negatives: the number of videos posted by verified accounts that the model misclassified as posted by unverified accounts.

The lower-right quadrant displays the number of true positives: the number of videos posted by verified accounts that the model accurately classified as so.

A perfect model would yield all true negatives and true positives, and no false negatives or false positives.

• Create a classification report that includes precision, recall, f1-score, and accuracy metrics to evaluate the performance of the logistic regression model.

```
[99]: # Create a classification report
target_labels = ["verified", "not verified"]
print(classification_report(y_test_final, y_pred, target_names=target_labels))
```

	precision	recall	f1-score	support
verified	0.74	0.52	0.61	4459
not verified	0.63	0.82	0.71	4483
			0. 47	0040
accuracy			0.67	8942
macro avg	0.69	0.67	0.66	8942
weighted avg	0.69	0.67	0.66	8942

Important note: The classification report above shows that the logistic regression model achieved a precision of 61% and a recall of 84%, and it achieved an accuracy of 65%. Note that the precision and recall scores are taken from the "not verified" row of the output because that is the target class that we are most interested in predicting. The "verified" class has its own precision/recall metrics, and the weighted average represents the combined metrics for both classes of the target variable.

2.0.10 Task 4c. Interpret model coefficients

```
[101]: # Get the feature names from the model and the model coefficients (which → represent log-odds ratios)

# Place into a DataFrame for readability

pd.DataFrame(data={"Feature Name":log_clf.feature_names_in_, "Model ∪ → Coefficient":log_clf.coef_[0]})
```

[101]:	Feature Name	Model Coefficient
0	video_duration_sec	-2.453635e-03
1	video_view_count	-1.688587e-07
2	video_share_count	4.826012e-06
3	video_download_count	-8.108520e-05
4	video_comment_count	4.482913e-04
5	claim_status_opinion	1.702595e+00
6	author_ban_status_banned	-4.484084e-01
7	author ban status under review	-9.866850e-02

2.0.11 Task 4d. Conclusion

- 1. What are the key takeaways from this project?
- 2. What results can be presented from this project?

Response:

Key takeaways:

• The dataset has a few strongly correlated variables, which might lead to multicollinearity issues when fitting a logistic regression model. We decided to drop video_like_count from the model building.

- Based on the logistic regression model, each additional second of the video is associated with 0.009 increase in the log-odds of the user having a verified status.
- The logistic regression model had not great, but acceptable predictive power: a precision of 61% is less than ideal, but a recall of 84% is very good. Overall accuracy is towards the lower end of what would typically be considered acceptable.

We developed a logistic regression model for verified status based on video features. The model had decent predictive power. Based on the estimated model coefficients from the logistic regression, longer videos tend to be associated with higher odds of the user being verified. Other video features have small estimated coefficients in the model, so their association with verified status seems to be small.
